Recap

Neural Networks: Key Facts

Supervised learning : we observe some data $S_{\text{train}} = \{x_n, y_n\}_{n=1}^N \in \mathcal{X} \times \mathcal{Y}$

➡ given a new x , we want to predict its label y

Linear prediction (with augmented features): $y = f_{\text{Lin}}(x) = \phi(x)^{\top} w$
Features are given

Prediction with a NN:

$y = f_{\text{NN}}(x) = f(x)^{\top} w$

Function implemented by the NN
parameters: weights and biases

First layers transform the input
into a good representation

Last layer is performing
a linear prediction

Fully Connected Neural Networks

$$x_j^{(l)} = \phi \left(\sum_{i=1}^K x_i^{(l-1)} w_{i,j}^{(l)} + b_j^{(l)} \right)$$

Important: ϕ is non-linear
otherwise we can only
represent linear functions

weight of the edge going from node i
in layer $l - 1$ to node j in layer l

bias term associated with
node j in layer l

NNs: Inference vs. Training

Linear prediction on features $f(x)$

$$h(x) = f(x)^\top w^{(L+1)} + b^{(L+1)}$$

Regression
with $y \in \mathbb{R}$

Binary Classification
with $y \in \{-1, 1\}$

Multi-Class Classification
with $y \in \{1, \dots, K\}$

Inference

$$h(x)$$

$$\text{sign}(h(x))$$

$$\operatorname{argmax}_{c \in \{1, \dots, K\}} h(x)_c$$

Training

$$\ell(y, h(x)) = (h(x) - y)^2$$

$$\ell(y, h(x)) = \log(1 + \exp(-yh(x)))$$

$$\ell(y, h(x)) = -\log \frac{e^{h(x)_y}}{\sum_{i=1}^K e^{h(x)_i}}$$

With a suitable representation of the data $f(x)$ learned by the network, the last layer only performs a linear regression or classification step

Today: How do we train a NN?

Training of NNs

Training loss for a regression problem with $S_{\text{train}} = \{(x_n, y_n)\}_{n=1}^N$:

$$\mathcal{L}(f) = \frac{1}{2N} \sum_{n=1}^N (y_n - f(x_n))^2$$

where f is the function represented by a NN with weights $(w_{i,j}^{(l)})$ and biases $(b_i^{(l)})$

Task:

$$\min_{w_{i,j}^{(l)}, b_i^{(l)}} \mathcal{L}(f)$$

Remarks:

- Regularization can be added to avoid overfitting and is easy to implement
- Non-convex optimization problem
 - ➡ not guaranteed to converge to a global minimum

Training of NNs with SGD

SGD algorithm: Uniformly sample n , compute the gradient of $\mathcal{L}_n = \frac{1}{2}(y_n - f(x_n))^2$ to update:

$$(w_{i,j}^{(l)})_{t+1} = (w_{i,j}^{(l)})_t - \gamma \frac{\partial}{\partial w_{i,j}^{(l)}} \mathcal{L}_n \quad (b_i^{(l)})_{t+1} = (b_i^{(l)})_t - \gamma \frac{\partial}{\partial b_i^{(l)}} \mathcal{L}_n$$

In Practice: Step size schedule, mini-batch, momentum, Adam

Training of NNs with SGD

SGD algorithm: Uniformly sample n , compute the gradient of $\mathcal{L}_n = \frac{1}{2}(y_n - f(x_n))^2$ to update:

$$(w_{i,j}^{(l)})_{t+1} = (w_{i,j}^{(l)})_t - \gamma \frac{\partial}{\partial w_{i,j}^{(l)}} \mathcal{L}_n \quad (b_i^{(l)})_{t+1} = (b_i^{(l)})_t - \gamma \frac{\partial}{\partial b_i^{(l)}} \mathcal{L}_n$$

In Practice: Step size schedule, mini-batch, momentum, Adam

Problem: With $O(K^2L)$ parameters, applying chain-rules **independently** is inefficient due to the compositional structure of f

Solution: the **Backpropagation algorithm** computes gradients via the chain rule but reuses intermediate computations

Description of NN parameters

Weight matrices: $\mathbf{W}^{(l)}$ such that $\mathbf{W}_{i,j}^{(l)} = w_{i,j}^{(l)}$, of size

- $\mathbf{W}^{(1)} \in \mathbb{R}^{d \times K}$
- $\mathbf{W}^{(l)} \in \mathbb{R}^{K \times K}$ for $2 \leq l \leq L$
- $\mathbf{W}^{(L+1)} \in \mathbb{R}^K$

Bias vectors: $b^{(l)}$ such that the i -th component is $b_i^{(l)}$

- $b^{(l)} \in \mathbb{R}^K$ for $1 \leq l \leq L$
- $b^{(L+1)} \in \mathbb{R}$

Compact description of output

The functions implemented by each layer can be written as:

- $x^{(1)} = f^{(1)}(x^{(0)}) := \phi\left((\mathbf{W}^{(1)})^\top x^{(0)} + b^{(1)}\right)$

...

- $x^{(l)} = f^{(l)}(x^{(l-1)}) := \phi\left((\mathbf{W}^{(l)})^\top x^{(l-1)} + b^{(l)}\right)$

...

- $y = f^{(L+1)}(x^{(L)}) := (\mathbf{W}^{(L+1)})^\top x^{(L)} + b^{(L+1)}$

The overall function $y = f(x^{(0)})$ is just the composition of the layer functions:

$$f = f^{(L+1)} \circ f^{(L)} \circ \dots \circ f^{(l)} \circ \dots \circ f^{(2)} \circ f^{(1)}$$

Cost function

Cost function:

$$\mathcal{L} = \frac{1}{2N} \sum_{n=1}^N \left(y_n - f^{(L+1)} \circ \dots \circ f^{(2)} \circ f^{(1)}(x_n) \right)^2$$

Remarks:

- The specific form of the loss is not crucial
- \mathcal{L} is a function of all weight matrices and bias vectors
- Each function $f^{(l)}$ is parameterized by weights $\mathbf{W}^{(l)}$ and biases $b^{(l)}$

Individual loss for SGD:

$$\mathcal{L}_n = \frac{1}{2} \left(y_n - f^{(L+1)} \circ \dots \circ f^{(2)} \circ f^{(1)}(x_n) \right)^2$$

Goal: Compute for all (i, j, l)

$$\frac{\partial \mathcal{L}_n}{\partial w_{i,j}^{(l)}} \quad \text{and} \quad \frac{\partial \mathcal{L}_n}{\partial b_i^{(l)}}$$

Chain rule

$$\mathcal{L}_n = \frac{1}{2} \left(y_n - f^{(L+1)} \circ \dots \circ f^{(l+1)} \circ \underbrace{\phi \left((\mathbf{W}^{(l)})^\top x^{(l-1)} + b^{(l)} \right)}_{z^{(l)}} \right)^2$$

$$\frac{\partial \mathcal{L}_n}{\partial w_{i,j}^{(l)}} \quad ?$$

Chain rule

$$\mathcal{L}_n = \frac{1}{2} \left(y_n - f^{(L+1)} \circ \dots \circ f^{(l+1)} \circ \phi(z^{(l)}) \right)^2$$

Apply the chain rule:

$$\frac{\partial \mathcal{L}_n}{\partial w_{i,j}^{(l)}} = \sum_{k=1}^K \frac{\partial \mathcal{L}_n}{\partial z_k^{(l)}} \frac{\partial z_k^{(l)}}{\partial w_{i,j}^{(l)}}$$

$$= \frac{\partial \mathcal{L}_n}{\partial z_j^{(l)}} \frac{\partial z_j^{(l)}}{\partial w_{i,j}^{(l)}}$$

$$= \frac{\partial \mathcal{L}_n}{\partial z_j^{(l)}} \cdot x_i^{(l-1)}$$

since $\frac{\partial z_k^{(l)}}{\partial w_{i,j}^{(l)}} = 0$ for $k \neq j$

since $z_j^{(l)} = \sum_{k=1}^K w_{k,j}^{(l)} x_k^{(l-1)} + b_j^{(l)}$

We need to compute $\frac{\partial \mathcal{L}_n}{\partial z_j^{(l)}}$, $z^{(l)}$, $x_i^{(l-1)}$ and reuse them for different $\frac{\partial \mathcal{L}_n}{\partial w_{i,j}^{(l)}}$

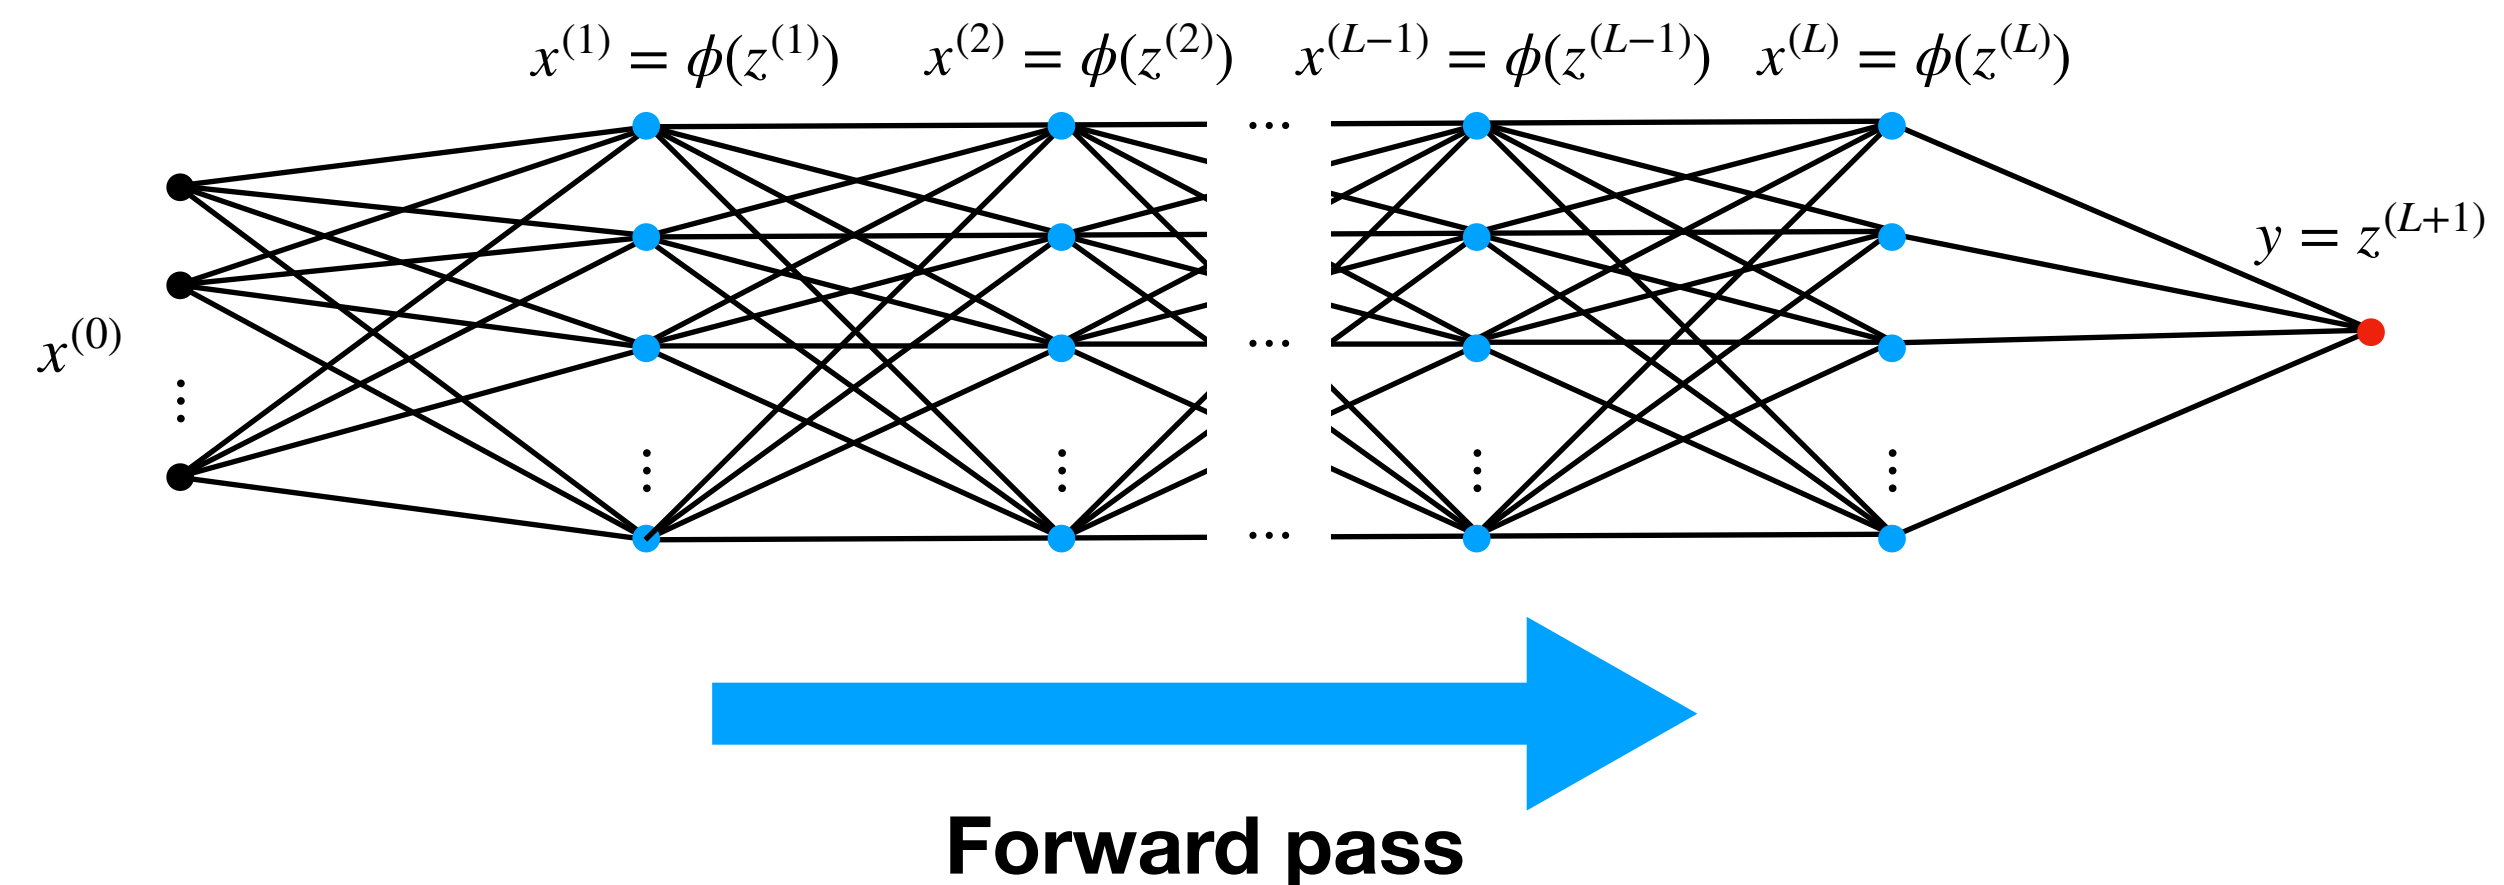

Forward Pass

We can compute $z^{(l)}$ and $x^{(l)}$ by a forward pass in the network:

$$x^{(0)} = x_n \in \mathbb{R}^d$$

$$z^{(l)} = (\mathbf{W}^{(l)})^\top x^{l-1} + b^{(l)}$$

$$x^{(l)} = \phi(z^{(l)})$$

Computational complexity:

➡ one pass over the network $O(K^2L)$

Backward pass (I)

Define $\delta_j^{(l)} = \frac{\partial \mathcal{L}_n}{\partial z_j^{(l)}}$

Chain rule:

$$\delta_j^{(l)} = \frac{\partial \mathcal{L}_n}{\partial z_j^{(l)}} = \sum_k \frac{\partial \mathcal{L}_n}{\partial z_k^{(l+1)}} \frac{\partial z_k^{(l+1)}}{\partial z_j^{(l)}} = \sum_k \delta_k^{(l+1)} \frac{\partial z_k^{(l+1)}}{\partial z_j^{(l)}}$$

Backward pass (II)

Using $z_k^{(l+1)} = \sum_{i=1}^K w_{i,k}^{(l+1)} x_i^{(l)} + b_k^{(l+1)} = \sum_{i=1}^K w_{i,k}^{(l+1)} \phi(z_i^{(l)}) + b_k^{(l+1)}$

We obtain $\frac{\partial z_k^{(l+1)}}{\partial z_j^{(l)}} = \phi'(z_j^{(l)}) w_{j,k}^{(l+1)}$

Thus $\delta_j^{(l)} = \sum_k \delta_k^{(l+1)} \phi'(z_j^{(l)}) w_{j,k}^{(l+1)}$

It can be written in vector form:

$$\delta^{(l)} = (\mathbf{W}^{(l+1)} \delta^{(l+1)}) \odot \phi'(z^{(l)})$$

\odot : Hadamard product, i.e.,
pointwise multiplication of vector

Backward pass (III)

Initialization:

$$\begin{aligned}\delta^{(L+1)} &= \frac{\partial}{\partial z^{(L+1)}} \frac{1}{2} (y_n - z^{(L+1)})^2 \\ &= z^{(L+1)} - y_n\end{aligned}$$

Compute all the $\delta^{(l)}$ by a backward pass in the network:

$$\delta^{(l)} = (\mathbf{W}^{(l+1)} \delta^{(l+1)}) \odot \phi'(z^{(l)})$$

Computational complexity: one pass over the network $O(K^2 L)$

Derivatives computation

Using that $z_m^{(l)} = \sum_{k=1}^K w_{k,m}^{(l)} x_k^{(l-1)} + b_m^{(l)}$:

$$\bullet \quad \frac{\partial \mathcal{L}_n}{\partial b_j^{(l)}} = \sum_{k=1}^K \frac{\partial \mathcal{L}_n}{\partial z_k^{(l)}} \frac{\partial z_k^{(l)}}{\partial b_j^{(l)}} = \frac{\partial \mathcal{L}_n}{\partial z_j^{(l)}} \frac{\partial z_j^{(l)}}{\partial b_j^{(l)}} = \delta_j^{(l)}$$

$$\bullet \quad \frac{\partial \mathcal{L}_n}{\partial w_{i,j}^{(l)}} = \sum_{k=1}^K \frac{\partial \mathcal{L}_n}{\partial z_k^{(l)}} \frac{\partial z_k^{(l)}}{\partial w_{i,j}^{(l)}} = \frac{\partial \mathcal{L}_n}{\partial z_j^{(l)}} \frac{\partial z_j^{(l)}}{\partial w_{i,j}^{(l)}} = \delta_j^{(l)} \cdot x_i^{(l-1)}$$

Backpropagation algorithm

Forward pass:

$$x^{(0)} = x_n \in \mathbb{R}^d$$

$$z^{(l)} = (\mathbf{W}^{(l)})^\top x^{l-1} + b^{(l)}$$

$$x^{(l)} = \phi(z^{(l)})$$

Backward pass:

$$\delta^{(L+1)} = z^{(L+1)} - y_n$$

$$\delta^{(l)} = (\mathbf{W}^{(l+1)} \delta^{(l+1)}) \odot \phi'(z^{(l)})$$

Compute the derivatives:

$$\frac{\partial \mathcal{L}_n}{\partial w_{i,j}^{(l)}} = \delta_j^{(l)} x_i^{(l-1)}$$

$$\frac{\partial \mathcal{L}_n}{\partial b_j^{(l)}} = \delta_j^{(l)}$$

Overall Complexity: $O(K^2L)$

Parameter Initialization

Importance of Parameter Initialization

- In deep networks, improper parameter initialization can lead to the **vanishing or exploding gradients problem**
- **Problem:** Extremely slow or unstable optimization
- **Solution:** Control the layerwise variance of activations (aka **He initialization**)
- **Note:** As illustrated, even a two-fold difference in the scale of initialization can be crucial

Variance-Preserving Initialization

Variance-Preserving initialization for ReLU networks:

- $x^{(l)} \in \mathcal{N}(0, \mathbf{I}_K)$: activations at layer l (note: $\text{Var}[x_i^{(l)}] = 1$)
- $w_i^{(l)} \in \mathcal{N}(0, \sigma \mathbf{I}_K)$: the i -th weight vector at layer l
- $x_i^{(l+1)} = \text{ReLU}((x^{(l)})^\top w_i^{(l)})$: the i -th activation at layer $l + 1$

Question: How should we set σ so that $\text{Var}[x_i^{(l+1)}] = 1$?

Answer: $\sigma = \sqrt{2/K}$

Derivation: Refer to the exercise for the derivation

Normalization Layers

Batch Normalization

Consider a batch $B = (x_1, \dots, x_M)$ and denote by $z_n^{(l)}$ the layer's pre-activation input corresponding to the observation x_n

Batch Normalization

Consider a batch $B = (x_1, \dots, x_M)$ and denote by $z_n^{(l)}$ the layer's pre-activation input corresponding to the observation x_n

One input x_n

Batch Normalization

Consider a batch $B = (x_1, \dots, x_M)$ and denote by $z_n^{(l)}$ the layer's pre-activation input corresponding to the observation x_n

Batch B of input x_1, \dots, x_M

$$(z_1^{(l)}, \dots, z_n^{(l)}, \dots, z_M^{(l)}) \in \mathbb{R}^{K \times M}$$

Batch Normalization

Consider a batch $B = (x_1, \dots, x_M)$ and denote by $z_n^{(l)}$ the layer's pre-activation input corresponding to the observation x_n

Step 1: Normalize each layer's input using its mean and its variance over the batch:

$$\bar{z}_n^{(l)} = \frac{z_n^{(l)} - \mu_B^{(l)}}{\sqrt{(\sigma_B^{(l)})^2 + \varepsilon}}$$

Component-wise

where $\mu_B^{(l)} = \frac{1}{M} \sum_{n=1}^M z_n^{(l)}$ and $(\sigma_B^{(l)})^2 = \frac{1}{M} \sum_{n=1}^M (z_n^{(l)} - \mu_B^{(l)})^2$, and $\varepsilon \in \mathbb{R}_{\geq 0}$ is a small value added for numerical stability

Step 2: Introduce learnable parameters $\gamma^{(l)}, \beta^{(l)} \in \mathbb{R}^K$ to be able to reverse the normalization if needed:

$$\hat{z}_n^{(l)} = \gamma^{(l)} \odot \bar{z}_n^{(l)} + \beta^{(l)}$$

Batch Normalization

Scale-invariance: For $\varepsilon \approx 0$, the output is invariant to activation-wise affine scaling of $z_n^{(l)}$

$$\text{BN}(a \odot z_n^{(l)} + b) = \text{BN}(z_n^{(l)}) \text{ for } a \in \mathbb{R}_{>0}^K \text{ and } b \in \mathbb{R}^K$$

Thus, for example, there is no need to include a bias *before* BatchNorm.

Inference: The prediction for one sample should not depend on other samples

- Estimate $\hat{\mu} = \mathbf{E}[\mu]$ and $\hat{\sigma} = \mathbf{E}[\sigma]$ during training, use these estimates for inference
- Exponential moving averages are commonly used in practice

Implementation:

- BatchNorm is applied a bit differently for non-fully-connected nets (see the [pytorch docs](#) for CNNs)
- In PyTorch, switch modes by using `model.train()` for training and `model.eval()` for inference

Batch Normalization - Results

Source: [Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift \(ICML 2015\)](#)

- BatchNorm leads to **much faster convergence**
- BatchNorm allows to use **much larger learning rates** (up to $30 \times$)

Layer Normalization

Step 1: Normalize each layer's input using its mean and its variance over *the activations* (instead of over *the inputs*):

$$\bar{z}_n^{(l)} = \frac{z_n^{(l)} - \mu_n^{(l)} \cdot 1_k}{\sqrt{(\sigma_n^{(l)})^2 + \varepsilon}}$$

where $\mu_n^{(l)} = \frac{1}{K} \sum_{k=1}^K z_n^{(l)}(k)$ and $(\sigma_n^{(l)})^2 = \frac{1}{K} \sum_{k=1}^K (z_n^{(l)}(k) - \mu_n^{(l)})^2$, and $\varepsilon \in \mathbb{R}_{\geq 0}$

Step 2: Introduce learnable parameters $\gamma^{(l)}, \beta^{(l)} \in \mathbb{R}^K$:

$$\hat{z}_n^{(l)} = \gamma^{(l)} \odot \bar{z}_n^{(l)} + \beta^{(l)}$$

Remarks:

- Normalize across activations, independently for each observation
- Very common alternative, widely used for transformers and text data
- No batch dependency, use the same for training and inference

Normalization - conclusion

Benefits of normalization layers:

- Stabilizes activation magnitudes / reduces initialization impact
- Additional regularization effect from noisy μ, σ in batch norm
- Stabilizes and speeds up training, allows larger learning rates

Used in almost all modern deep learning architectures

- Often inserted after every convolutional layer, before non-linearity

Recap

- Neural networks are trained with gradient-based methods such as **SGD**
- To compute the gradients, we use **backpropagation**, which involves the chain rule to efficiently calculate the gradients based on the network's intermediate outputs $z^{(l)}$ and $\delta^{(l)}$
- Proper **parameter initialization** should avoid exploding and vanishing gradients by carefully controlling the layerwise variance
- **Batch and Layer normalization** dynamically stabilize the training process, allowing for faster convergence and the use of larger learning rates
